Hydroxytyrosol (3,4 dihydroxyphenylethanol; 3,4-DHPEA or HT), the most abundant phenolic compound in extra virgin olive oil (EVOO) plays a significant role in cardiovascular diseases (CVDs) protection and its metabolites are able to protect from the endothelial dysfunction commonly present in atherosclerosis. This randomized double-blinded, placebo-controlled crossover trial study was carried out to determine the effect in healthy volunteers of two gastro-resistant capsules containing 15mg/day of HT, for a 3-week period (HTT). Evaluation of nutritional, serum metabolites, oxidative stress biomarkers and gene expression of 9 genes related to oxidative stress, inflammation and CVDs was performed. Oxidation biomarkers like thiols groups ($p= 0.000$), total antioxidant status (TAS) ($p= 0.00$), superoxide dismutase-1 (SOD1) ($2-\Delta\Delta Ct = 3.7$) and plasma concentration of HT (2.83 mg mL^{-1}) were significantly increased, while nitrite ($p= 0.00$), nitrate ($p= 0.001$) and malondialdehyde (MDA) ($p= 0.02$) were drastically reduced after HTT. A significant reduction of body fat mass percentage ($p= 0.01$), suprailiac skinfold ($p= 0.01$) and weight ($p= 0.04$; $\Delta\% = -0.46\%$) was observed after HTT. Results show that regular intake of 15 mg/day of HT changed body composition parameters, modulated anti-oxidant profile and the expression of inflammation and oxidative-stress-related genes. However, it is advisable a personalization of HT doses in order to exert its health benefits in CVDs prevention and protection of LDL-C particles from oxidative damage.
